COMPLETE THE STN SURVEY - APRIL 27 THROUGH MAY 31

Dear valued STN customer,

In an effort to enhance your experience with STN, we would like to better understand what you find useful. Please take approximately 5 minutes to complete a web survey.

If you provide us with your name, login ID, and e-mail address, you will be entered in a drawing to win a free iPod(R). Your responses will be kept confidential and will help us make future improvements to STN.

Take survey: <http://www.zoomerang.com/survey.zgi?p=WEB2259HNKWTUW>

Thank you in advance for your participation.

AB The present invention relates to luminescent inorg. **nanoparticles**
comprising (a) a core made from a first metal salt or oxide being
surrounded by (b) a shell made from a second metal salt or oxide being
luminescent and having non-semiconductor properties. These particles can
be advantageously used in (fluorescence) resonance energy transfer
((F)RET)-based bioassays in view of their higher (F)RET efficiency.

AB The present invention concerns procedures for the synthesis of **nanoparticles**, especially metal salt **nanoparticles**, and in particular the chemical modification their surfaces to attach functional groups providing properties required for future use. According to the invention the addition of a modifying agent to the synthesis mixture leads to attachment of a 1st functional group to the **nanoparticle** surface which is then bonded to specifically selected mols. carrying a 2nd functional group. Thus a post synthetic, sep. use-specific modification step is unnecessary. Advantageously addition of a 3rd functional group is possible. A new substance class, the imino-bis(methylenephosphono)carboxylic acid pentaalkyl esters, are particularly suitable as modifying agents. These modifying agents permit the growth of the **nanoparticles** with controlled and simultaneous modification of the surface during synthesis (in situ) in such a way that the particles are very soluble in a multiplicity of solvents, and can be used for coupling of mols. with functional groups, e.g., antibodies; the particles possess an all around usefulness.

AB The invention relates to an assay based on resonance energy transfer (RET), comprising a 1st mol. group A, which is marked with ≥ 1 energy donor, and ≥ 1 2nd mol. group B which is marked with ≥ 1 energy acceptor, the donor comprising a mol. or particle which can be energetically excited by an external radiation source and which is fluorescence enabled and the acceptor comprising a mol. or particle which can be excited by energy transfer via the donor with partial or complete quenching of the donor fluorescence, and the donor and/or acceptor comprise luminescing inorg. doped **nanoparticles** having an expansion of ≤ 50 nm, emitting electromagnetic radiation with stokes or anti-stokes scattering after energetic excitation. Thus LaPO₄:Ce,Tb nanoparticles were synthesized; the nanoparticles were treated with ethylene glycol and sulfuric acid at 210 °C in inert gas atmospheric for 3 h. The particles were dissolved

at ca. 135°C; ethylene glycol was partially evaporated and the solution was dialyzed over night against water. The surface treated **nanoparticles** underwent oxidation with potassium permanganate in the presence of sulfuric acid for carboxy functionalization.

AB Iron oxide **nanoparticles** are used in vivo as contrast agents in magnetic resonance imaging. Their widely used polymer coatings are directly involved in their biocompatibility and avoid magnetic aggregation. As these polymer brushes also limit their tissue diffusion due to important hydrodynamic sizes, this work looks to obtain particles coated with thin layers of organic biocompatible mols. Coating mols. were chosen depending on their fixation site on iron cores; carboxylates, sulfonates, phosphates, and phosphonates, and, among them, analogs of the phosphorylcholine. Two coating procedures (dialysis and exchange resins purification) were evaluated for hydrodynamic size, total iron concentration, electrophoretic mobility, and colloidal stability. Furthermore, a complementary test on stainless steel plates evaluated the contamination by competition of phosphonates as a rough estimation of the biocompatibility of

the particles. Coating with bisphosphonates, the more interesting fixation moiety, leads to small (less than 15 nm) and stable objects in a wide range of pH including the neutrality. From stability data, the coating d. was evaluated at around 1.6 mols. per nm². Including a quaternary ammonium salt to the coating mol. lowers their electrophoretic mobility. Moreover, this type of coating protects steel plates against contamination without significant desorption. All these properties allow further developments of these **nanoparticles** for biomedical applications. (c) 2001 Academic Press.

 DOCUMENT TYPE: Conference; Meeting Abstract; (computer optical disk)
 LANGUAGE: English
 AB Magnetic **nanoparticles** consisting of **undecanoate** -capped magnetite were used to control and switch the hydrophobic or hydrophilic properties of the electrode surface. The magnetic attraction

of the functionalized **nanoparticles** to the electrode surface by means of an external magnet yields a hydrophobic interface that acts as insulating layer prohibiting interfacial electron transfer. The retraction of the magnetic **nanoparticles** from the electrode to the upper toluene phase by means of the external magnet generates a hydrophilic electrode that reveals effective interfacial electron transfer. This was used to switch reversibly bioelectrocatalytic reactions. The hydrophobic magnetic **nanoparticles** were also used to control biorecognition and biocatalytic processes on biomaterial-functionalized interfaces, such as DNA hybridization, polymerization and scission.

AB The present invention relates to an orally administrable composition containing **nanoparticles** with the particle size of 500 nm or less, comprising 0.130 weight% of a complex of a water-soluble drug and a counter-ion substance in which the charged water-soluble drug is bonded with the counter-ion substance, 0.5-80 weight% of a lipid, 0.5-80 weight% of a polymer, and 1-80 weight%

of an emulsifier, wherein the weight ratio of said lipid and said polymer is in the range of 1:0.053, and a preparation method thereof. The composition of the

present invention has high gastrointestinal absorption rate upon oral administration, and has high drug entrapping rate in the **nanoparticle**, and is also stable against lipases. For example, oral **nanoparticles** contained insulin-sodium docusate complex 15, monoolein 60, chitosan 20, Poloxamer 407 200 mg, and small amount of citric acid.

AB The present invention is directed to compns. of one or more nanoparticulate active agents, at least one PEG-derivatized surface stabilizer, and at least one antibody or fragment thereof, and methods of using such compns. for targeting delivery of the one or more active agents to a desired site. The one or more active agents preferably have a particle size of $\leq 2 \mu$. The targeted delivery can be used, e.g., for disease diagnosis, imaging, or drug delivery. Thud, WIN-68209 particles wee stabilized by PEG-DSPE stabilizer.

AB Magnetic **nanoparticles** consisting of **undecanoate** -capped magnetite (average diameter .apprx.5 nm) are used to selectively gate diffusional and surface-confined electrochem. reactions. A two-phase system consisting of an aqueous buffer solution and a toluene phase that includes

the suspended **undecanoate**-capped magnetic **nanoparticles** is used to control the interfacial properties of the electrode surface. Two different phenomena are controlled by attraction of the magnetic **nanoparticles** to the electrode by means of an external magnet: (i) The attracted magnetic **nanoparticles** form a hydrophobic layer on the electrode surface resulting in the blocking of diffusional electrochem. processes, while retaining the redox functions of surface-confined electrochem. units. (ii) For certain surface-immobilized redox species (e.g., quinones), the attraction of the magnetic

nanoparticles to the electrode surface alters the mechanism of the process from an aqueous-type electrochem. to a dry organic-phase-type electrochem. Also, bioelectrocatalytic and electrocatalytic transformations at the electrode are controlled by means of attraction of the magnetic **nanoparticles** to the electrode surface. Controlling the catalytic functions of the modified electrode by means of the magnetic **nanoparticles** attracted to the electrode is exemplified in two different directions: (i) Blocking of the bioelectrocatalyzed oxidation of glucose by glucose oxidase (GOx) using a surface-confined ferrocene monolayer as electron-transfer mediator. (ii) Activation of the microperoxidase-11 electrocatalyzed reduction of cumene hydroperoxide. In the latter system, the hydrophobic magnetic **nanoparticles** adsorb toluene, and the hydrophobic matrix acts as a carrier for cumene hydroperoxide to the electrode surface modified with the microperoxidase-11 catalyst.

AB Disclosed are compds. that include two or more haptens conjugated by a spacer or a carrier. The haptens may include diethylenetriaminepentaacetate (DTPA), histamine-succinyl-glutamine (HSG), or combinations of DTPA and HSG. The compds. also includes an effector mol. which may be conjugated to one or more of the haptens, the

spacer/carrier, or both. The effector mol. may be conjugated by a number of linkages including an ester linkage, an imino linkage, an amino linkage, a sulfide linkage, a thiosemicarbazone linkage, a semicarbazone linkage, an oxime linkage, an ether linkage, or combinations of these linkages. Also disclosed are methods of synthesizing the compds. and/or precursors of the compds.

AB Magnetic **nanoparticles** consisting of **undecanoate**

-capped magnetite (average diameter .apprx.4.5 nm; saturated magnetization,
Ms, 38.5

emu g⁻¹) are used to control and switch the hydrophobic or hydrophilic properties of the electrode surface. A 2-phase system consisting of an aqueous buffer solution and a toluene phase that includes the suspended capped magnetic **nanoparticles** is used to control the interfacial properties of the electrode surface. The magnetic attraction of the functionalized particles to the electrode by an external magnet yields a hydrophobic interface that acts as an insulating layer, prohibiting interfacial electron transfer. The retraction of the magnetic particles from the electrode to the upper toluene phase by the external magnet generates a hydrophilic electrode that reveals effective interfacial electron transfer. The electron-transfer resistance and double-layer capacitance of the electrode surface upon the attraction and retraction of the functionalized magnetic particles to and from the electrode, resp., by the external magnet were probed by Faradaic impedance spectroscopy (Ret = 170 Ω and Cdl = 40 $\mu\text{F cm}^{-2}$ in the hydrophilic state of the electrode and Ret = 22 k Ω and Cdl = 0.5 $\mu\text{F cm}^{-2}$ in the hydrophobic state of the interface). The magnetoswitchable control of the interface enables magnetic switching of the bioelectrocatalytic oxidation of glucose in the presence of glucose oxidase and ferrocene dicarboxylic acid to ON and OFF states.

AB Photosensitizer/electron acceptor mol. cross-linked Au-
nanoparticle arrays are assembled on indium-doped tin oxide (ITO)
electrodes by a layer-by-layer deposition process. A Ru(II)-tris-(2,2'-

bipyridine)-cyclobis(paraquat-p-phenylene) catenane (1) or Zn(II)-protoporphyrin IX-bis(N-methyl-N'-undecanoate -4,4'-bipyridinium) (2) are used as mol. cross-linkers for the generation of Au-nanoparticle (13 ± 1 nm) arrays of a controlled number of layers. The Au-nanoparticle arrays are characterized by absorbance spectroscopy and by electrochem. means. The electrodes functionalized with 1- or 2-cross-linked Au-nanoparticle arrays are used in photoelectrochem. expts. The resulting action spectra of the photocurrents follow the absorbance spectra of the resp. chromophores. Mechanistic studies indicate that the photocurrents originate from intramol. electron-transfer quenching of the photoexcited state of the photosensitizer by the electron acceptor units, leading to the formation of intermediate redox species. The oxidized photoproduct oxidizes the sacrificial electron donor, Na2EDTA, whereas the reduced bipyridinium radical cations transfer the electrons to the bulk electrode support.
